Dear MongoDB Hiring Team,

I'm drawn to MongoDB's Software Engineer Intern role because I want to contribute to a data platform that powers real innovation at scale. Your unified data platform sits at the intersection of software architecture and customer impact, and I'm excited to push production-level code that serves both your internal teams and the developers building on MongoDB Atlas. The opportunity to work on systems that handle globally distributed data for 75% of the Fortune 100 appeals to me far more than generic "learn industry practices" internships.

I've built systems that demand exactly the architectural thinking MongoDB values. On SleepPool, I designed a TypeScript monorepo with a shared pure-logic core handling settlement math, a 7-state pool lifecycle state machine, and 5 anti-cheat heuristics, verified by 55 unit tests. I engineered a deterministic, idempotent settlement engine over an append-only ledger with a provable money-conservation invariant, then built durable scheduled jobs (Inngest) that automatically lock and settle pools. That work required the same attention to correctness, state management, and system reliability I'd need contributing to production MongoDB services. On my automated YouTube pipeline, I built end-to-end Python systems orchestrated with cron that ran 100+ consecutive days without manual intervention, handling data-driven logic, error recovery, and real-time alerting. Both projects show I can write reliable, tested code that scales.

I'm ready to write production code from day one and treat an internship as real work, not resume padding. I graduate May 2028, so I'll have two semesters post-internship to push what I learned further.

Sincerely,
James Hose
